1 Introduction

The main purpose of the PDFT_EX project was to create an extension of T_EX that can create PDF directly from T_EX source files and improve/enhance the result of T_EX typesetting with the help of PDF. When PDF output is not selected, PDFT_EX produces normal DVI output, otherwise it produces PDF output that looks identical to the DVI output. An important aspect of this project is to investigate alternative justification algorithms, optionally making use of multiple master fonts.

PDFT_EX is based on the original T_EX sources and Web2c, and has been successfully compiled on Unix, Win32 and MSDos systems. It is still under beta development and all features are liable to change. Despite its β -state, PDFT_EX produces excellent PDF code.

As PDFT_EX evolves, this manual will evolve and more background information will be added. Be patient with the authors.

This manual is typeset in CONTEXT. One can generate an A4 version from the source code by saying:

texexec pdftex-t

An letter size variant is also supported:

texexec --mode=letter pdftex-t

Given that the A4 version is typeset, one can generate a booklet by saying:

This also demonstrates that PDFT_EX can be used for page imposition purposes (given that PDFT_EX and the fonts are set up all right).

We thank all readers who send us corrections and suggestions. We also wish to express the hope that PDFTEX will be of as much use to you as it is to us. Since PDFTEX is still being improved and extended, we suggest you keep track of updates.

2 About PDF

The cover of this manual shows a simple PDF file. Unless compression and/or encryption is applied, such a file is rather verbose and readable. The first line specifies the version used; currently PDFT_EX produces level 1.2 output. Viewers are supposed to silently skip over all elements they cannot handle.

A PDF file consist of objects. These objects can be recognized by their number and keywords:

Here 8 0 obj ... endobj is the object capsule. The first number is the object number. Later we will see that PDF T_EX gives access to this number. One can for instance create an object by using \pdfobj after which \pdflastobj returns the number. So

```
\pdfobj{/Type /Catalog /Pages 6 0 R}
```

inserts an object into the file, while \pdflastobj returns the number $pdfl_EX$ assigned to this object. The sequence 6 0 R is an object reference, a pointer to another object. The second number (here a zero) is currently not used in $pdfl_EX$; it is the version number of the object. It is for instance used by pdflex when they replace objects by new ones.

In general this rather direct way of pushing objects in the files is rather useless and only makes sense when implementing for instance fill-in field support or annotation content reuse. We will come to that later. Unless such direct objects are part of something larger, they will end up as isolated entities, not doing any harm but not doing any good either.

When a viewer opens a PDF file, it first goes to the end of the file. There it finds the keyword startxref, the signal where to look for the so called 'object cross reference table'. This table provides fast access to the objects that make up the file. The actual starting point of the file is defined after the trailer. The /Root entry points to the catalog. In this catalog the viewer can find the page list. In our example we have only one page. The trailer also holds an /Info entry, which tells a bit more about the document. Just follow the thread:

 $/Root \rightarrow object 8 \rightarrow /Pages \rightarrow object 6 \rightarrow /Kids \rightarrow object 2 \rightarrow page content$

As soon as we add annotations, a fancy word for hyperlinks and alike, some more entries are present in the catalog. We invite users to take a look at the PDF code of this file to get an impression of that.

The page content is a stream of drawing operations. Such a stream can be compressed, where the level of compression can be set with \pdfcompresslevel. Let's take a closer look at this stream. First there is a transformation matrix, six numbers followed by cm. As in PostScript, the operator comes after the operands. Between BT and ET comes the text. A font switch can be recognized as /F... The actual text goes between () so that it creates a PostScript string. When one analyzes a file produced by a less sophisticated typesetting engine, whole sequences of words can be recognized. In TeX however, the text comes out rather fragmented, mainly because a lot of kerning takes place. Because viewers can search in these streams, one can imagine that the average TeX produced files becomes more difficult as soon as the typesetting engine does a better job; TeX cannot do less.

This one page example uses an Adobe Times Roman font. This is one of the 14 fonts that is always present in the viewer application, and is called a base font. However, when we use for instance Computer Modern Roman, we have to make sure that this font is available, and the best way to do this is to embed it in the file.

Just let your eyes follow the object thread and see how a font is described. The only thing missing in this example is the (partially) embedded glyph description file, which for the base fonts is not needed.

In this simple file, we don't specify in what way the file should be opened, for instance full screen or clipped. A closer look at the page object (/Type /Page) shows that a mediabox is part of the page description. A mediabox acts like the bounding box in a POSTSCRIPT file. PDFTEX users have access to this object by \pdfpageattr.

Although in most cases macro packages will shield users from these internals, PDFT_EX provides access to many of the entries described here, either automatically by translating the T_EX data structures into PDF ones, or manually by pushing entries to the catalog, page, info or self created objects. Those who, after this introduction, feel uncomfortable in how to proceed, are advised to read on but skip section 7. Before we come to that section, we will describe how to get started with PDFT_EX.

3 Getting started

This section describes the steps needed to get PDF T_EX running on a system where PDF T_EX is not yet installed. Some T_EX distributions have PDF T_EX as a component, like T_ET_EX , T_ET_EX , T_ET_EX , T_ET_EX , T_EX ,

For some years there has been a 'moderate' successor to T_EX available, called E- T_EX . Because the main stream macro packages start supporting this welcome extension, PDF T_EX also is available as PDFE- T_EX . Although in this document we will speak of PDF T_EX , we advise users to use PDFE- T_EX when available. That way they get the best of all worlds and are ready for the future.

3.1 Getting sources and binaries

The latest sources of PDFTEX are distributed together with precompiled binaries of PDFTEX for some plat-

forms, including Linux¹, SGI IRIX, Sun SPARC Solaris and MSDos (DJGPP).² The primary location where one can fetch the source code (by version) is:

```
ftp://ftp.cstug.cz/pub/tex/local/cstug/thanh/pdftex/latest
```

Thomas Esser's TET_EX distribution comes with precompiled versions for many UNIX systems. More information can be found at: http://www.tug.org/teTeX. For WIN32 systems (Windows 95, Windows NT) there are two packages that contain PDFT_EX, both in ctan:systems/win32: FPT_EX, maintained by Fabrice Popineau, popineau@ese-metz.fr, and MIKTEX by Christian Schenk, cschenk@berlin.snafu.de.

3.2 Compiling

If there is no precompiled binary of PDFT_EX for your system, you need to build PDFT_EX from sources. The compilation is expected to be easy on UNIX-like systems and can be described best by example. Assuming that all needed files are downloaded to \$HOME/pdftex, on a UNIX system the following steps are needed to compile PDFT_EX:

```
cd $HOME/pdftex
gunzip < web-7.3.tar.gz | tar xvf -
gunzip < web2c-7.3.tar.gz | tar xvf -
gunzip < pdftex.tar.gz | tar xvf -
mv pdftexdir web2c-7.3/web2c
cd web2c-7.3
./configure
cd web2c
make pdftex</pre>
```

¹The Linux binary is compiled for the new 1ibc-6 (GNU glibc-2.0), which will not run for users of older Linux installations still based on libc-5.

²The DJGPP version is built by DJGPP 2.0 cross-compiler on Linux.

If you happen to have a previously configured source tree and just install a new version of PDFT_EX, you can avoid running configure from the top-level directory. It's quicker to run config.status, which will just regenerate the Makefile's based on config.cache:

cd web2c-7.3/web2c sh config.status make pdftex

For Unix users the savest way to generate binaries is to get the latest TET_EX and follow the instructions that come with it.

Apart from the binary of PDF T_EX the compilation also produces several other files which are needed for running PDF T_EX :

pdftex.pool The pool file, needed for creating formats, located in web2c-7.3/web2c

texmf.cnf WEB2C run-time configuration file, located in web2c-7.3/kpathsea

ttf2afm An external program to generate AFM files from TrueType fonts, located in web2c-7.3/web2c/pdftexdir

Precompiled binaries are included in the ZIP archive pdftex.zip.

3.3 Getting PDFT_FX-specific platform-independent files

Apart from the above-mentioned files, there is another ZIP archive (pdftexlib.zip) in the PDFT_EX distribution which contains platform-independent files required for running PDFT_EX:

- configuration file: pdftex.cfg
- encoding vectors: *.enc
- map files: *.map
- macros: *.tex

Unpacking this archive —don't forget the -d option when using pkunzip— will create a texmf tree containing PDFT_EX-specific files.

3.4 Placing files

The next step is to place the binaries somewhere in PATH. If you want to use LTEX, you also need to make a copy (or symbolic link) of pdftex and name it pdflatex. The files texmf.cnf and pdftex.pool and the directory texmf, created by unpacking the file pdftexlib.zip, should be moved to the 'appropriate' place (see below).

3.5 Setting search paths

Web2c-based programs, including PDFT_EX, use the Web2c run-time configuration file called texmf.cnf. This file can be found via the user-set environment variable TEXMFCNF or via the compile-time default value if the former is not set. It is strongly recommended to use the first option. Next you need to edit texmf.cnf so PDFT_EX can find all necessary files. Usually one has to edit TEXMFS and maybe some of the next variables. When running PDFT_EX, some extra search paths are used beyond those normally requested by T_EX itself:

VFFONTS Virtual fonts are fonts made up of others and vf files play an important role in this

process. Because PDFTEX produces the final output code, it must consult those files.

T1FONTS Outline (vector) fonts are to be prefered over bitmap PK fonts. In most cases Type 1 fonts

are used and this variable tells PDFT_FX where to find them.

TTFONTS Like Type 1 fonts, TrueType fonts are also outlines.

MISCFONTS PDFT_EX is able to read so called pdf glyph container files. These contain fonts de-

scriptions in PDF format. (A separate manual will be made available soon.)

used for	format	texmf.cnf
virtual fonts	kpse_vf_format	VFFONTS
type1 fonts	kpse_type1_format	T1FONTS
truetype fonts	kpse_truetype_format	TTFONTS
pgc fonts	kpse_miscfonts_format	MISCFONTS
pdftex.cfg	kpse_tex_format	TEXINPUTS
images	kpse_tex_format	TEXINPUTS
map files	kpse_tex_ps_header_format	TEXPSHEADERS
encoding files	kpse_tex_ps_header_format	TEXPSHEADERS

Table 1 The Web2C variables.

PKFONTS	Unfortunately bitmap fonts are displayed poorly by PDF viewers, so when possible one should use outline fonts. When no outline is available, PDFTEX tries to locate a suitable PK font (or invoke a process that generates them).
TEXINPUTS	This variable specifies where $\mathtt{PDFT}_E\!X$ finds its configuration file and input files. Being a postprocessor too, image files are considered input files and searched for along this path.
TEXPSHEADERS	This is the path where PDFT _E X looks for the font mapping files (*.map) and encoding files (*.enc). Both types provide PDFT _E X the information needed for embedding font encoding vectors and font resources.

3.6 The PDFT_EX configuration file

One has to keep in mind that, opposed to DVI output, there is no postprocessing stage. This has several rather fundamental consequences, like one-pass graphic and font inclusion. When T_{EX} builds a page, the macro

package used quite certain has a concept of page dimensions, which is not the same as paper dimensions. The reference point of the page is the top-left corner.

Most DVI postprocessors enable the user to specify the paper size, which often defaults to 'A4' or 'letter'. In most cases it does not harm that much to mix the two, because one will seldom put too small paper in the printer. And, if one does, one will certainly not do that a second time. In PDF the paper size is part of the definition. This means that everything that is off page, is clipped off, it simply disappears. Even worse, just like in a POSTSCRIPT file, the reference point is in the lower corner, which is opposite to DVI's reference point.

And so, we've found one of the main reasons why PDFT_EX explicitly needs to know the paper dimensions. These dimensions can either be passed using the so called configuration file, or by using the primitives provided for this purpose. In this respect, the PDFT_EX configuration file can be compared to configuration files that come with DVI postprocessors and/or command line options. Both contain information on the paper used, the fonts to be included and optimizations to be applied.

When PDFTEX is run in ini—mode, which is normally the case when we generate a format file, the configuration file is not read at all, and all configuration parameters are set to 0 by default for both integer and dimension parameters.

When PDFT_EX is launched in non-ini mode, it reads the Web2C configuration file as well as the PDFT_EX configuration file called pdftex.cfg, searched for in the TEXINPUTS path. As Web2C systems commonly specify a 'private' tree for PDFT_EX where configuration and map files are located, this allows individual users or projects to maintain customized versions of the configuration file. The configuration file must exist when PDFT_EX is run (except when generating a format).

The integer configuration parameters replace the corresponding internal ones just before $PDFT_{E}X$ starts reading the input file. At this moment the format is already loaded, so any former settings during creating formats will be overwritten by the values from config file. So, unless the macro package used resets

\pdfoutput, PDFTEX will produce PDF output! Macros (packages) that adapt themselves to either DVI (using specials) or PDF (dedicated primitives) should be aware of this.

When at the moment the first page is shipped out \pdfoutput has positive value, the configuation parameters that are dimension overwrite only the corresponding internal ones that are 0. The value of \pdfoutput cannot be changed after the first page has been shipped out.

Most parameters in the configuration file have a corresponding internal register. When not set during the T_{FX} run, $PDFT_{FX}$ uses the values as specified in the configuration file.

internal name	parameters	type
\pdfoutput	output_format	integer
\pdfadjustspacing	adjust_spacing_level	integer
\pdfcompresslevel	compress_level	integer
\pdfdecimaldigits	decimal_digits	integer
\pdfmovechars	move_chars	integer
\pdfimageresolution	image_resolution	integer
\pdfpkresolution	pk_resolution	integer
\pdfhorigin	horigin	dimension
\pdfvorigin	vorigin	dimension
\pdfpageheight	page_height	dimension
\pdfpagewidth	page_width	dimension
\pdflinkmargin	link_margin	dimension
\pdfthreadmargin	thread_margin	dimension

Figure 1 The configuration parameters.

Apart from the above described parameters, the configuration file can have another entry named map. This

entry specifies the font mapping files, which is similar to those used by many DVI to POSTSCRIPT drivers. More than one map file can be specified, using multiple map lines. If the name of the map file is prefixed with a +, its values are appended to the existing set, otherwise they replace it. If no map files are given, the default value psfonts.map is used.

A typical pdftex.cfg file looks like this, setting up output for A4 paper size and the standard T_EX offset of 1 inch, and loading two map files for fonts:

```
% the implicit output will be PDF
output_format
                   1
compress_level
                              % use the fastest level of compression
                   1
decimal_digits
                              % max. 3 digits after the decimal point
                              % when not specified, embed images at 300 DPI
image_resolution
                   300
                              % use PK fonts at 600 DPT
pk_resolution
                   600
move_chars
                  1
                              % move chars in 0..31 to higher area
page_width
                  210 true mm % A4 paper width
                  297 true mm % A4 paper height
page_height
horigin
                  1 true in % horizontal origin offset
vorigin
                  1 true in % vertical origin offset
                   pdftex.map % standard map file
map
                  +misc.map
                              % map file for extra fonts
map
```

The configuration file sets default values for these parameters, and apart from the map entry, they all can be over-ridden in the TEX source file. Dimensions can be specified as true, which makes them immune for magnification (when set).

output_format This integer parameter specifies whether the output format should be DVI or PDF. A positive value means PDF output, otherwise we get DVI output.

compress_level This integer parameter specifies the level of text and in-line graphics compression. PDFT_EX uses zIP compression as provided by zlib. A value of 0 means no compression, 1 means fastest, 9 means

best, 2..8 means something in between. Just set this value to 9, unless there is a good reason to do otherwise -0 is great for testing macros that use \pdfliteral .

decimal_digits This integer specifies the preciseness of real numbers in PDF page descriptions. It gives the maximal number of decimal digits after the decimal point of real numbers. Valid values are in range 0..5. A higher value means more precise output, but also results in a much larger file size and more time to display or print. In most cases the optimal value is 2. This parameter does *not* influence the precision of numbers used in raw PDF code, like that used in \pdfliteral and annotation action specifications.

image_resolution When PDFT_EX is not able to determine the natural dimensions of an image, it assumes a resolution of type 72 dots per inch. Use this variable to change this default value.

pk_resolution One can use this entry to specify the resolution for bitmap fonts. Nowadays most printers are capable to print at least 600 dots per inch, so this is a reasonable default.

move_chars Although PDF output is claimed to be portable, especially when all font information is included in the file, problems with printing and viewing have a persistent nature. Moving the characters in range 0-31 sometimes helps a lot. When set to 1, characters are only moved when a font has less than 128 glyphs, when set to 2 higher slots are used too.

page_width & page_height These two dimension parameters specify the output medium dimensions (the paper, screen or whatever the page is put on). If they are not specified, the page width is calculated as $w_{\text{box being shipped out}} + 2 \times (\text{horigin} + \text{hoffset})$. The page height is calculated in a similar way.

horigin & vorigin These dimension parameters can be used to set the offset of the T_EX output box from the top left corner of the 'paper'.

map This entry specifies the font mapping file, which is similar to those used by many DVI to POSTSCRIPT drivers. More than one map file can be specified, using multiple map lines. If the name of the map file is prefixed with a +, its values are appended to the existing set, otherwise they replace it. If no map files are given, the default value psfonts.map is used.

3.7 Creating formats

Formats for PDFTEX are created in the same way as for TeX. For plain TeX and LaTeX it looks like:

```
pdftex -ini -fmt=pdftex plain \dump
pdftex -ini -fmt=pdflatex latex.ltx
```

In ConT_EXT the generation depends on the interface used. A format using the english user interface is generated with

```
pdftex -ini -fmt=cont-en cont-en
```

When properly set up, one can also use the $ConT_EXT$ command line interface T_EXEXEC to generate one or more formats, like:

```
texexec --make en
```

for an english format, or

```
texexec --make --tex=pdfetex en de
```

for an english and german one, using PDFE-T_EX. Indeed, if there is PDFT_EX as well as PDFE-T_EX, use it! Whatever macro package used, the formats should be placed in the TEXFORMATS path. We strongly recommend to use PDFE-T_EX, if only because the main stream macro packages (will) use it.

3.8 Testing the installation

When everything is set up, you can test the installation. In the distribution there is a plain T_EX test file example.tex. Process this file by saying:

```
pdftex example
```

If the installation is ok, this run should produce a file called example.pdf. The file example.tex is also a good place to look for how to use PDFTEX's new primitives.

3.9 Common problems

The most common problem with installations is that PDFT_EX complains that something cannot be found. In such cases make sure that TEXMFCNF is set correctly, so PDFT_EX can find texmf.cnf. The next best place to look/edit is the file texmf.cnf. When still in deep trouble, set KPATHSEA_DEBUG=255 before running PDFT_EX

Variables in texmf.cnf can be overwritten by environment variables. Here are some of the most common problems you can encounter when getting started:

or run PDFT_FX with option -k 255. This will cause PDFT_FX to write a lot of debugging information that can

be useful to trace problems. More options can be found in the Web2C documentation.

- I can't read pdftex.pool; bad path?
 - TEXMFCNF is not set correctly and so PDFT_EX cannot find texmf.cnf, or TEXPOOL in texmf.cnf doesn't contain a path to the pool file pdftex.pool or pdfetex.pool when you use PDFE-T_EX.
- You have to increase POOLSIZE.

PDFT_EX cannot find texmf.cnf, or the value of pool_size specified in texmf.cnf is not large enough and must be increased. If pool_size is not specified in texmf.cnf then you can add something like

$$pool_size = 500000$$

• I can't find the format file 'pdftex.fmt'!

I can't find the format file 'pdflatex.fmt'!

Format is not created (see above how to do that) or is not properly placed. Make sure that TEXFORMATS in texmf.cnf contains the path to pdftex.fmt or pdflatex.fmt.

Fatal format file error; I'm stymied.

This appears if you forgot to regenerate the .fmt files after installing a new version of the PDFTEX binary and pdftex.pool.

- TEX.POOL doesn't match; TANGLE me again!

 TEX.POOL doesn't match; TANGLE me again (or fix the path).
 - This might appear if you forgot to install the proper pdftex.pool when installing a new version of the PDFT_EX binary.
- PDFT_EX cannot find the configuration file pdftex.cfg, one or more map files (*.map), encoding vectors (*.enc), virtual fonts, Type 1 fonts, TrueType fonts or some image file.

Make sure that the required file exists and the corresponding variable in texmf.cnf contains a path to the file. See above which variables PDF T_EX needs apart from the ones T_EX uses.

Normally the page content takes one object. This means that one seldom finds more than a few hundred objects in a simple file. This document for instance uses about 300 objects. In demanding applications this number can grow quite rapidly, especially when one uses a lot of widget annotations, shared annotations or other shared things. In these situations in texmf.cnf one can enlarge PDFTEX's internal object table by adding a line in texmf.cfg, for instance:

 $obj_tab_size = 400000$

4 Macro packages supporting PDFT_FX

When producing DVI output, for which one can use PDFT_EX as well as any other T_EX, part of the job is delegated to the DVI postprocessor, either by directly providing this program with commands, or by means of \specials. Because PDFT_EX directly produces the final format, it has to do everything itself, from handling color, graphics, hyperlink support, font-inclusion, upto page imposition and page manipulation.

As a direct result, when one uses a high level macro package, the macros that take care of these features have to be set up properly. Specials for instance make no sense at all. Actually being a comment understood by DVI postprocessors—given that the macro package speaks the specific language of this postprocessor—

a \special would end up as just a comment in the PDF file, which is of no use. Therefore, \special issues a warning when PDFT_EX is in PDF mode.

When one wants to get some insight to what extend PDFT_EX specific support is needed, one can start a file by saying:

```
\pdfoutput=1 \let\special\message
```

or, if this leads to confusion,

```
\pdfoutput=1 \def\special#1{\write16{special: #1}}
```

And see what happens. As soon as one 'special' message turns up, one knows for sure that some kind of PDFT_EX specific support is needed, and often the message itself gives a indication of what is needed.

Currently all main stream macro packages offer PDFT_EX support in one way or the other. When using such a package, it makes sense to turn on this support in the appropriate way, otherwise one cannot be sure if things are set up right. Remember that for instance the page and paper dimensions have to be taken care of, and only the macro package knows the details.

- For LATEX users, Sebastian Rahtz' hyperref package has substantial support for PDFTEX, and provides access to most of its features. In the simplest case, the user merely needs to load hyperref with a pdftex option, and all cross-references will be converted to PDF hypertext links. PDF output is automatically selected, compression is turned on, and the page size is set up correctly. Bookmarks are created to match the table of contents.
- The standard MEX graphics and color packages have pdftex options, which allow use of normal color, text rotation, and graphics inclusion commands.
- The ConT_EXT macro package by Hans Hagen (pragma@wxs.nl) has very full support for PDFT_EX in its generalized hypertext features. Support for PDFT_EX is implemented as a special driver, and is invoked by saying \setupoutput[pdftex] or feeding T_EXEXEC with the --pdf option.

- Hypertexted PDF from texinfo documents can be created with pdftexinfo.tex, which is a slight modification of the standard texinfo macros. This file is part of the PDFTFX distribution.
- A similar modification of webmac.tex, called pdfwebmac.tex, allows production of hypertext'd PDF versions of programs written in WEB. This is also part of the PDFTFX distribution.

Some nice samples of PDFT $_{E}X$ output can be found on the TUG web server, at http://www.tug.org/applications/pdftex and http://www.ntg.nl/context.

5 Setting up fonts

PDFT_EX can work with Type 1 and TrueType fonts, but a source must be available for all fonts used in the document, except for the 14 base fonts supplied by Acrobat Reader (Times, Helvetica, Courier, Symbol and Dingbats). It is possible to use METAFONT-generated fonts in PDFT_EX— but it is strongly recommended not to use METAFONT-fonts if an equivalent is available in Type 1 or TrueType format, if only because bitmap Type 3 fonts render very poorly in Acrobat Reader. Given the free availability of Type 1 versions of all the Computer Modern fonts, and the ability to use standard PostScript fonts, most T_EX users should be able to experiment with PDFT_EX.

5.1 Map files

PDFT_EX reads the map files, specified in the configuration file, see section 3.6, in which reencoding and partial downloading for each font are specified. Every font needed must be listed, each on a separate line, except PK fonts. The syntax of each line is similar to dvips map files³ and can contain up to the following (some are optional) fields: *texname*, *basename*, *fontflags*, *fontfile*, *encodingfile* and *special*. The only mandatory is *texname* and must be the first field. The rest is optional, but if *basename* is given, it must be the second

³dvips map files can be used with PDFT_EX without problems.

field. Similarly if *fontflags* is given it must be the third field (if *basename* is present) or the second field (if *basename* is left out). It is possible to mix the positions of *fontfile*, *encodingfile* and *special*, however the first three fields must be given in fixed order.

texname sets the name of the TFM file. This name must be given for each font.

basename sets the base (POSTSCRIPT) font name. If not given then it will be taken from the font file. Specifying a name that doesn't match the name in the font file will cause PDFT_EX to write a warning, so it is best not to have this field specified if the font resource is available, which is the most common case. This option is primarily intended for use of base fonts and for compatibility with dvips map files.

fontflags specify some characteristics of the font. The next description of these flags are taken, with a slight modification, from the PDF Reference Manual (the section on Font Descriptor Flags).

The value of the flags key in a font descriptor is a 32-bit integer that contains a collection of boolean attributes. These attributes are true if the corresponding bit is set to 1. Table 2 specifies the meanings of the bits, with bit 1 being the least significant. Reserved bits must be set to zero.

All characters in a *fixed-width* font have the same width, while characters in a proportional font have different widths. Characters in a *serif font* have short strokes drawn at an angle on the top and bottom of character stems, while sans serif fonts do not have such strokes. A *symbolic font* contains symbols rather than letters and numbers. Characters in a *script font* resemble cursive handwriting. An *all-cap* font, which is typically used for display purposes such as titles or headlines, contains no lowercase letters. It differs from a *small-cap* font in that characters in the latter, while also capital letters, have been sized and their proportions adjusted so that they have the same size and stroke weight as lowercase characters in the same typeface family.

Bit 6 in the flags field indicates that the font's character set conforms the Adobe Standard Roman Character Set, or a subset of that, and that it uses the standard names for those characters.

bit position	semantics
1	Fixed-width font
2	Serif font
3	Symbolic font
4	Script font
5	Reserved
6	Uses the Adobe Standard Roman Character Set
7	Italic
8-16	Reserved
17	All-cap font
18	Small-cap font
19	Force bold at small text sizes
20-32	Reserved

Table 2 The meaning of flags in the font descriptor.

Finally, bit 19 is used to determine whether or not bold characters are drawn with extra pixels even at very small text sizes. Typically, when characters are drawn at small sizes on very low resolution devices such as display screens, features of bold characters may appear only one pixel wide. Because this is the minimum feature width on a pixel-based device, ordinary non-bold characters also appear with one-pixel wide features, and cannot be distinguished from bold characters. If bit 19 is set, features of bold characters may be thickened at small text sizes.

If the font flags are not given, PDFT_EX treats it as being 4, a symbolic font. If you do not know the correct value, it would be best not to specify it, as specifying a bad value of font flags may cause troubles in viewers. On the other hand this option is not absolutely useless because it provides backward compatibility with older map files (see the fontfile description below).

fontfile sets the name of the font source file. This must be a Type 1 or TrueType font file. The font file name can be preceded by one or two special characters, which says how the font file should be handled.

- If it is preceded by a < the font file will be partly downloaded, which means that only used glyphs (characters) are embedded to the font. This is the most common use and is *strongly recommended* for any font, as it ensures the portability and reduces the size of the PDF output. Partial fonts are included in such a way that name and cache clashes are minimalized.
- In case the font file name is preceded by a double <<, the font file will be included entirely all glyphs of the font are embedded, including the ones that are not used in the document. Apart from causing large size PDF output, this option may cause troubles with TrueType fonts too, so it is not recommended. It might be useful in case the font is untypical and can not be subsetted well by PDFTEX. Beware: some font vendors forbid full font inclusion.
- In case nothing preceded the font file name, the font file is read but nothing is embedded, only the font parameters are extracted to generate the so-called font descriptor, which is used by Acrobat Reader to simulate the font if needed. This option is useful only when you do not want to embed the font (i.e. to reduce the output size), but wish to use the font metrics and let Acrobat Reader generate instances that look close to the used font in case the font resource is not installed on the system where the PDF output will be viewed or printed. To use this feature the font flags *must* be specified, and it must have the bit 6 set on, which means that only fonts with the Adobe Standard Roman Character Set can be simulated. The only exception is in case of Symbolic font, which is not very useful.
- If the font file name is preceded by a !, the font is not read at all, and is assumed to be available on the system. This option can be used to create PDF files which do not contain embedded fonts. The PDF output then works only on systems where the resource of the used font is available. It's not very useful for document exchange, as the PDF is not 'portable' at all. On the other hand it is very useful when you wish to speed up running of PDFTEX during interactive work, and only in a final version embed all used fonts. Don't over-estimate gain in speed and when distributing files, always embed the fonts! This

feature requires Acrobat Reader to have access to installed fonts on the system. This has been tested on Win95 and UNIX (Solaris).

Note that the standard 14 fonts are never downloaded, even when they are specified to be downloaded in map files. When one suffers from invalid lookups, for instance when PDFTEX tries to open a .pfa file instead of a .pfb one, one can add the suffix to the filename. In this respect, PDFTEX completely relies on the kpathsea libraries.

encoding specifies the name of the file containing the external encoding vector to be used for the font. The file name may be preceded by a <, but the effect is the same. The format of the encoding vector is identical to that used by dvips. If no encoding is specified, the font's built-in default encoding is used. It may be omitted if you are sure that the font resource has the correct built-in encoding. In general this option is highly preferred and is *required* when subsetting a TrueType font.

special instructions can be used to manipulate fonts similar to the way dvips does. Currently only the keyword SlantFont is interpreted, other instructions are just ignored.

If a used font is not present in the map files, first $PDFT_{E}X$ will look for a source with suffix .pgc, which is a so-called PGC source (PDF Glyph Container)⁴. If no PGC source is available, PDFT_EX will try to use PK fonts in a normal way as DVI drivers do, on-the-fly creating PK fonts if needed.

Lines containing nothing apart from *texname* stand for scalable Type 3 fonts. For scalable fonts as Type 1, TrueType and scalable Type 3 font, all the fonts loaded from a TFM at various sizes will be included only once in the PDF output. Thus if a font, let's say csr10, is described in one of the map files, then it will be treated as scalable. As a result the font source for csr10 will be included only once for csr10, csr10 at 12pt etc.

⁴This is a text file containing a PDF Type 3 font, created by METAPOST using some utilities by Hans Hagen. In general PGC files can contain whatever allowed in PDF page description, which may be used to support fonts that are not available in METAFONT. At the moment PGC fonts are not very useful, as vector Type 3 fonts are not displayed very well in Acrobat Reader, but it may be more useful when Type 3 font handling gets better.

So PDFTEX tries to do its best to avoid multiple downloading of identical font sources. Thus vector PGC fonts should be specified as scalable Type 3 in map files like:

It doesn't hurt much if a scalable Type 3 font is not given in map files, except that the font source will be downloaded multiple times for various sizes, which causes a much larger PDF output. On the other hand if a font is in the map files is defined as scalable Type 3 font and its PGC source is not scalable or not available, PDFTEX will use PK font instead; the PDF output is still valid but some fonts may look ugly because of the scaled bitmap.

A SlantFont is specified similarly as for dvips. A SlantFont or ExtendFont must be used with embedding font file. Note that the base name, the POSTSCRIPT name like Symbol or Times-Roman, cannot be given, as PDFT_EX never embeds a base font.

```
psyr Symbol
psyro ".167 SlantFont" <usyr.pfb
ptmr8r Times-Roman <8r.enc</pre>
```

To summarize this rather confusing story, we include some sample lines. First we use a built-in font with font-specific encoding, i.e. neither a download font nor an external encoding is given.

```
psyr Symbol
pzdr ZapfDingbats
```

Use a built-in font with an external encoding. The < preceded encoding file may be left out.

```
ptmr8r Times-Roman <8r.enc
ptmri8r Times-Italic <8r.enc</pre>
```

Use a partially downloaded font with an external encoding:

Use some faked font map entries:

```
<logo8.pfb
logo8
logo9
           <loqo9.pfb
logo10
           <loqo10.pfb
logos18
           <le><logo8.pfb</li>
                        ".25 SlantFont"
logos19
          <le><logo9.pfb</li>
                            ".25 SlantFont"
logos110
         <logos110.pfb
logobf10
           <logobf10.pfb</li>
```

Use an ASCII subset of OT1 and T1:

```
ectt1000 cmtt10 <cmtt10.map <tex256.enc
```

Download a font entirely without reencoding:

```
pgsr8r GillSans <<pgsr8a.pfb
```

Partially download a font without reencoding:

```
pgsr8r GillSans <pgsr8a.pfb
```

Do not read the font at all — the font is supposed to be installed on the system:

```
pgsr8r GillSans !pgsr8a.pfb
```

Entirely download a font with reencoding:

```
pgsr8r GillSans <<pgsr8a.pfb 8r.enc
```

Partially download a font with reencoding:

pgsr8r GillSans <pgsr8a.pfb 8r.enc

Sometimes we do not want to include a font, but need to extract parameters from the font file and reencode the font as well. This only works for fonts with Adobe Standard Encoding. The font flags specify how such a font looks like, so Acrobat Reader can generate similar instance if the font resource is not available on the target system.

pgsr8r GillSans 32 pgsr8a.pfb 8r.enc

A TrueType font can be used in the same way as a Type 1 font:

verdana8r Verdana <verdana.ttf 8r.enc

5.2 TrueType fonts

As mentioned above, $PDFT_{E}X$ can work with TrueType fonts. Defining TrueType files is similar to Type 1 font. The only extra thing to do with TrueType is to create a TFM file. There is a program called ttf2afm in the PDFT_EX distribution which can be used to extract AFM from TrueType fonts. Usage is simple:

ttf2afm -e <encoding vector> -o <afm outputfile> <ttf input file>

A TrueType file can be recognized by its suffix ttf. The optional *encoding* specifies the encoding, which is the same as the encoding vector used in map files for PDFTEX and dvips. If the encoding is not given, all the glyphs of the AFM output will be mapped to /.notdef. ttf2afm writes the output AFM to standard output. If we need to know which glyphs are available in the font, we can run ttf2afm without encoding to get all glyph names. The resulting AFM file can be used to generate a TFM one by applying afm2tfm.

To use a new TrueType font the minimal steps may look like below. We suppose that test.map is included in pdftex.cfg.

```
ttf2afm -e 8r.enc -o times.afm times.ttf
afm2tfm times.afm -T 8r.enc
echo "times TimesNewRomanPSMT <times.ttf <8r.enc" >>test.map
```

The PostScript font name (TimesNewRomanPSMT) is reported by afm2tfm, but from PDFT_EX version 0.12l onwards it may be left out.

There are two main restrictions with TrueType fonts in comparison with Type 1 fonts:

- a. The special effects SlantFont/ExtendFont cannot be used.
- b. To subset a TrueType font, the font must be specified as reencoded, therefore an encoding vector must be given.

6 Formal syntax specification

This sections formaly specifies the PDFT_EX specific extensions to the T_EX macro programming language. First we present some general definitions. All \langle general text \rangle is expanded immediately, like \rangle special in traditional T_EX, unless mentioned explicitly no to.

```
\langle goto-action spec \rangle \rightarrow \langle numid \rangle \mid
       [ \langle file spec \rangle ] \langle nameid \rangle |
       [\langle file spec \rangle | \langle page spec \rangle \langle general text \rangle
       (file spec) (nameid) (newwindow spec)
       (file spec) (page spec) (general text) (newwindow spec)
\langle numid \rangle \rightarrow num \langle integer \rangle
\langle nameid \rangle \rightarrow name \langle general text \rangle
\langle \text{thread-action spec} \rangle \rightarrow [\langle \text{file spec} \rangle] \langle \text{numid} \rangle \mid [\langle \text{file spec} \rangle] \langle \text{nameid} \rangle
\langle dest \ spec \rangle \rightarrow \langle numid \rangle \langle dest \ type \rangle \mid \langle nameid \rangle \langle dest \ type \rangle
\langle \text{dest type} \rangle \rightarrow \text{xyz} [\text{zoom } \langle \text{integer} \rangle] |
       fitbh | fitbv | fitb | fith | fitv | fitr (rule spec) | fit
\langle id \ spec \rangle \rightarrow \langle numid \rangle \mid \langle nameid \rangle
PDFT<sub>F</sub>X introduces the following new primitives. Each primitive is prefixed by pdf except for \efcode and
the extended font primitive.
\pdfoutput (integer)
\pdfcompresslevel (integer)
\pdfdecimaldigits (integer)
\pdfmovechars (integer)
\pdfpkresolution (integer)
\pdfpagewidth (dimension)
\pdfpageheight (dimension)
\pdfhorigin (dimension)
\pdfvorigin (dimension)
\pdfpagesattr (tokens)
\pdfpageattr (tokens)
\pdfinfo \( \text{general text} \)
```

```
\pdfcatalog \( \text{general text} \) \[ \text{openaction \( \action spec} \) \]
\pdfnames \( \text \)
\font [\langle font spec \rangle ] [stretch \langle integer \rangle ] [shrink \langle integer \rangle ] [step \langle integer \rangle ]
\pdfadjustspacing (integer)
\efcode (integer)
\pdffontname \( \font \) (expandable)
\pdffontobjnum \( \font \rangle \) (read-only integer)
\pdfincludechars \( \font \) \( \text{general text} \)
\pdfxform [\langle attr spec \rangle ] [\langle resources spec \rangle ] \langle box number \rangle
\pdfrefxform \(\)integer\\
\pdflastxform (read-only integer)
\pdfximage [\langle rule spec\rangle ] [\langle attr spec\rangle ] [\langle page spec\rangle ] \langle file spec\rangle
\pdfrefximage \(\rangle\) integer\
\pdflastximage (read-only integer)
\pdfimageresolution (integer)
\pdfannot [\langle rule spec \rangle ] \langle general text \rangle
\pdflastannot (read-only integer)
\pdfdest \dest spec\
\pdfstartlink [\langle rule spec \rangle ] [\langle attr spec \rangle ] \langle action spec \rangle
\pdfendlink
\pdflinkmargin (dimension)
\pdfoutline \action spec \ [ count \langle integer \rangle ] \langle general text \rangle
\pdfthread \langle rule spec \rangle [\langle attr spec \rangle ] \langle id spec \rangle
\pdfthreadmargin (dimension)
\pdfliteral [direct] \( \text{general text} \)
\pdfobj [ \langle object type spec \rangle ] \langle general text \rangle
```

\pdflastobj (read-only integer) \pdfrefobj \(\)integer\\ \pdftexversion (read-only integer) \pdftexrevision (expandable)

New primitives

Here follows a short description of new primitives added by PDFTFX. One way to learn more about how to use these primitives is to have a look at the file example.tex in the PDFT_EX distribution. Each PDFT_EX specific primitive is prefixed by \pdf.

The parameters that are marked as *default: from configuration* take their value from the configuration file. Note that if the output is DVI then the dimension parameters are not set to the configuration values and not used at all. However some PDFT_FX integer parameters can affect the PDF as well as DVI output (currently \pdfoutput and \pdfadjustspacing).

\pdfoutput (integer)

This parameter specifies whether the output format should be DVI or PDF. A positive value means PDF output, otherwise one gets DVI output. This parameter cannot be specified *after* shipping out the first page. In other words, this parameter must be set before PDFT_FX ships out the first page if we want PDF output. This is the only one parameter that must be set to produce PDF output. All others are optional. This parameter cannot be set after the first page is shipped out.

When PDFT_EX starts complaining about specials, one can be sure that the macro package is not aware of this mode. A simple way of making macros PDFT_FX aware is:

\ifx\pdfoutput\undefined \csname newcount\endcsname\pdfoutput \fi

However, there are better ways to handle these things.

\pdfcompresslevel (integer)

This integer parameter specifies the level of text compression via zlib. Zero means no compression, 1 means fastest, 9 means best, 2..8 means something in between. A value out of this range will be adjusted to the nearest meaningful value. This parameter is read each time PDFT_EX starts a stream.

► \pdfdecimaldigits (integer)

This parameter specifies the accuracy of real numbers as written to the in PDF file. It gives the maximal number of decimal digits after the decimal point of real numbers. Valid values are in range 0..5. A higher value means a more precise output, but also results in a much larger file size and more time to display or print. In most cases the optimal value is 2. This parameter does not influence the precision of numbers used in raw PDF code, like that used in \pdfliteral and annotation action specifications. This parameter is read when PDFTEX writes a real number to the PDF output.

When including huge METAPOST images using supp-pdf.tex, one can limit the accuracy to two digits by saying: \twodigitMPoutput.

▶ \pdfmovechars (integer)

This parameter specifies whether PDFT_EX should try to move characters in range 0..31 to higher slots. When set to 1, this feature affects only to fonts that have all character codes below 128, which applies to for instance the Computer Moderd Roman fonts. When set to 2 or higher PDFT_EX will try to move those characters to free slots in encoding array, even in case the font contains characters with code greater than or equal to 128. This parameter is read when PDFT_EX writes a character of a font to the PDF output at which moment it has to decide whether to move the character or not.

► \pdfpkresolution (integer)

This integer parameter specifies the default resolution of embedded PK fonts and is read when PDFTEX downloads a PK font during finishing the PDF output. Currently bitmap fonts are displayed poorly, so use Type 1 fonts when available!

► \pdfpagewidth (dimension)

This dimension parameter specifies the page width of the PDF output, being the screen, the paper or whatrever the page content is put on. PDFT_EX reads this parameter when it starts shipping out a page. When at this moment the value is still 0, the page width is calculated as $w_{\text{box being shipped out}} + 2 \times (\text{horigin} + \text{hoffset})$.

Like the next one, this value replaces the value set in the configuration file. When part of the page falls of the paper or screen, you can be rather sure that this parameter is set wrong.

► \pdfpageheight (dimension)

Similar to the previous one, this dimension parameter specifying the page height of the PDF output. If not given then the page height will be calculated as mentioned above.

► \pdfhorigin (dimension)

This parameter can be used to set the horizontal offset the output box from the top left corner of the page. A value of 1 inch corresponds to the normal TeX offset. This parameter is read when PDFTeX starts shippin gout a page to the PDF outout.

▶ \pdfvorigin (dimension)

This parameter is the vertical alternative of \pdfhorigin. Keep in mind that the TeX coordinate system starts in the top left corner, while the PDF one starts at the bottom.

► \pdfpagesattr (tokens)

PDFT_EX expands this token list when it finishes the PDF output and adds the resulting character stream to the root Pages object. When sound, these are applied to all pages in the document. Some examples of attributes

are /MediaBox, the rectangle specifying the natural size of the page, /CropBox, the rectangle specifying the region of the page being displayed and printed, and /Rotate, the number of degrees (in multiples of 90) the page should be rotated clockwise when it is displayed or printed.

► \pdfpageattr (tokens)

This is similar to \pdfpagesattr, but it takes priority to the former one. It can be used to overwrite any attribute given by \pdfpagesattr for individual pages. The token list is expanded when PDFTEX ships out a page. The contents are added to the attributes of the current page.

7.2 The document info and catalog

► \pdfinfo ⟨general text⟩

This primitive allows the user to add information to the document info section; if this information is provided, it can be extracted by Acrobat Reader (version 3.1: menu option *Document Information, General*). The (general text) is a collection of key-value-pairs. The key names are preceded by a /, and the values, being strings, are given between parentheses. All keys are optional. Possible keys are /Author, /CreationDate (defaults to current date), /ModDate, /Creator (defaults to TeX), /Producer (defaults to pdfTeX), /Title, /Subject, and /Keywords.

/CreationDate and /ModDate are expressed in the form D:YYYYMMDDhhmmss, where YYYY is the year, MM is the month, DD is the day, hh is the hour, mm is the minutes, and ss is the seconds.

Multiple appearances of \pdfinfo will be concatenated to only one. If a key is given more than once, then the first appearance will take priority. An example of the use of \pdfinfo is:

```
\pdfinfo
  { /Title
                  (example.pdf)
    /Creator
                  (TeX)
    /Producer
                  (pdfTeX 0.14a)
    /Author
                  (Tom and Jerry)
    /CreationDate (D:19980212201000)
    /ModDate
                  (D:19980212201000)
    /Subject
                  (Example)
    /Keywords
                  (mouse,cat) }
```

\pdfcatalog \(\) general text \(\) [openaction \(\) action spec \(\)]

Similar to the document info section is the document catalog, where keys are /URI, which provides the base URL of the document, and /PageMode determines how Acrobat displays the document on startup. The possibilities for the latter are explained in Table 3:

value	meaning
/UseNone	neither outline nor thumbnails visible
/UseOutlines	outline visible
/UseThumbs	thumbnails visible
/FullScreen	full-screen mode

Table 3 Supported / PageMode values.

In full-screen mode, there is no menu bar, window controls, nor any other window present. The default setting is /UseNone.

The (openaction) is the action provided when opening the document and is specified in the same way as internal links, see section 7.7. Instead of using this method, one can also write the open action directly into the catalog.

This primitive inserts the text to /Names array. The text must be conform to the specifications as laid down in the PDF Reference Manual, otherwise the document can be invalid.

7.3 Fonts

\font [\langle font spec \rangle] [stretch \langle integer \rangle] [shrink \langle integer \rangle] [step \langle integer \rangle]

Although still in an experimental stage, and therefore subjected to changes, the next extension to the T_EX primitive font is worth mentioning.

\font\somefont=somefile at 10pt stretch 30 shrink 20 step 10

The stretch 30 shrink 20 step 5 means as much as: "hey T_EX, when things are going to bad, you may stretch the glyphs in this font as much as 3% or shrink them by 2%". Because PDFT_EX uses internal datastructures with fixed widths, each additional width also means an additional font. For practical reasons PDFT_EX uses discrete steps, in this example a 1% one. This means that for font somefile upto 6 differently scaled alternatives are used. When no step is specified, 0.5% steps are used.

Roughly spoken, the trick is as follows. Consider a text typeset in triple column mode. When T_EX cannot break a line in the appropriate way, the unbreakable parts of the word will stick into the margin. When PDFT_EX notes this, it will try to scale (shrink) the glyphs in that line using fixed steps, until the line fits. When lines are too spacy, the opposite happens: PDFT_EX starts scaling (stretching) the glyphs until the white space gaps is acceptable.

The additional fonts are named as somefile+10 or somefile-15, and TFM files with these names and appropriate dimensions must be available. So, each scaled font must have its own TFM file! When no TFM file can be found, PDFTEX will try to generate it by executing the script mktextfm, where available and supported.

Y

This mechanism is inspired on an optimization first introduced by Herman Zapf, which in itself goes back to optimizations used in the early days of typesetting: use different glyphs to optimize the greyness of a page. So, there are many, slightly different a's, e's, etc. For practical reasons PDFTEX does not use such huge glyph collections; it uses horizontal scaling instead. This is sub-optimal, and for many fonts, sort of offending to the design. But, when using PDF, it's not that illogical at all: PDF viewers use so called Multiple Master fonts when no fonts are embedded and/or can be found on the target system. Such fonts are designed to adapt their design to the different scaling parameters. It is up to the user to determine to what extend mixing slightly remastered fonts can be used without violating the design. Think of an O: when simply stretched, the vertical part of the glyph becomes thicker, and looks incompatible to an unscaled original. In a multiple master, one can decide to stretch but keep this thickness compatible.

\pdfadjustspacing (integer)

The output that PDFTEX produces is pretty compatible with the normal TeX output: TeX's typesetting engine is normally unchanged, because the optimization described here is turned off by default. At this moment there are two methods provided. When \pdfadjustspacing is set to 1, stretching is applied *after* TeX's normal paragraph breaking routines have broken the paragraph into lines. In this case, line breaks are identical to standard TeX behaviour.

When set to 2, the width changes that are the result of stretching and shrinking are taken into account *while* the paragraph is broken into lines. In this case, line breaks are likely to be different from those of standard T_EX. In fact, paragraphs may even become longer or shorter.

Both alternatives use the extended collection of TFM files that are related to the stretch and shrink settings as described in the previous section.

► \efcode (integer)

We didn't yet tell the whole story. One can imagine that some glyphs are more sensitive to scaling than others. The \efcode primitive can be used to influence the stretchability of a glyph. The syntax is similar to \sfcode, and defaults to 1000, meaning 100%.

\efcode'A=2500 \efcode'0=0

In this example an A may stretch 2.5 times as much as normal and the O is not to be stretched at all. The minimum and maximum stretch is however bound by the font specification, otherwise one would end up with more fonts inclusions than comfortable.

► \pdffontname \(\lambda\) (expandable)

In PDF files produced by PDF T_EX , one can recognize a font switch by the prefix F followed by a number, for instance /F12 or /F54. This command returns the number PDF T_EX uses to name a font resource, e.g. for a font named as /F12 this command returns number 12.

► \pdffontobjnum \(font \) \((read-only integer \)

This command is similar to \pdffontname, but returns the object number instead of the name of a font. Use of \pdffontname and \pdffontobjnum allows user full access to all the font resources used in the document.

▶ \pdfincludechars \(font \) \(general text \)

This command causes PDFTEX to treat the characters in $\langle general \; text \rangle$ as if they were used with $\langle font \rangle$, which means that the corresponding glyphs will be embedded into the font resources in the PDF output. Nothing is appended to the list being built.

7.4 XObject forms

The next three primitives support a PDF feature called 'object reuse' in PDFT_EX. The idea is first to create a XObject form in PDF. The content of this object corresponds to the content of a T_EX box, which can also contain pictures and references to other XObject form objects as well. After that the XObject form can be used by simply referring to its object number. This feature can be useful for large documents with a lot of similar elements, as it can reduce the duplication of identical objects.

These command behave similar \pdfobj, \pdflastobj and \pdfrefobj but instead of taking raw PDF code, they take care of text typeset by T_FX.

► \pdfxform [\(\attr \text{spec} \)] [\(\text{resources spec} \)] \(\text{box number} \)

This command creates a XObject form corresponding to the contents of the box $\langle box number \rangle$. The box can contain other raw objects, XObject forms or images as well. It can however *not* contain annotations because they are laid out on a separate layer, are positioned absolutely, and have a dedicated housekeeping.

When \langle attr spec \rangle is given, the text will be written as additional attributes of the form. The \langle resources spec \rangle is similar, but the text will be added to the resources dictionary of the form. The text given by \langle attr spec \rangle or \langle resources spec \rangle is written before other keys of the form dictionary and/or the resources dictionary and takes priority to the further ones.

► \pdfrefxform ⟨integer⟩

The form is kept in memory and will be written to the PDF output only when its number is referred to by \pdfrefxform or \pdfxform is preceded by \immediate. Nothing is appended to the list being built. The number of the most recently created XObject form is accessible via \pdflastxform.

When issued, $\protect\protec$

\pdflastxform (read-only integer)

The number of the most recently created XObject form is accessible via \pdflastxform.

As said, this feature can be used for reusing information. This mechanism also plays a role in typesetting fill-in form. Such widgets sometimes depends on visuals that show up on user request, but are hidden otherwise.

7.5 Graphics inclusion

PDF provides a mechanism for embedding graphic and textual objects: XObject forms. In PDF T_EX this mechanism is accessed by means of \pdfxform, \pdflastxform and \pdfrefxform. A special kind of XObjects are bitmap graphics and for manipulating them similar commands are provided.

\pdfximage [\langle rule spec \rangle] [\langle attr spec \rangle] [\langle page spec \rangle] \langle file spec \rangle

This command creates an image object. The dimensions of the image can be controlled via $\langle \text{rule spec} \rangle$. The default values are zero for depth and 'running' for height and width. If all of them are given, the image will be scaled to fit the specified values. If some of them (but not all) are given, the rest will be set to a value corresponding to the remaining ones so as to make the image size to yield the same proportion of width:(height+depth) as the original image size, where depth is treated as zero. If none of them is given then the image will take its natural size.

An image inserted at its natural size often has a resolution of \pdfimageresolution (see below) given in dots per inch in the output file, but some images may contain data specifying the image resolution, and in such a case the image will be scaled to the correct resolution. The dimension of the image can be accessed by enclosing the \pdfrefximage command to a box and checking the dimensions of the box:

\setbox0=\hbox{\pdfximage{somefile.png}\pdfrefximage\pdflastximage}

Now we can use \wd0 and \ht0 to question the natural size of the image as determined by PDFTEX. When dimensions are specified before the {somefile.pdf}, the graphic is scaled to fit these. Opposite to for instance the \input primitive, the filename is supplied between braces.

The image type is specified by the extension of the given file name, so .png stands for PNG image, tif for TIFF, and .pdf for PDF file. Otherwise the image is treated as PDF (pdf).

Similarly to \pdfxform, the optional text given by \(attr spec\) will be written as additional attributes of the image before other keys of the image dictionary.

► \pdfrefximage ⟨integer⟩

The image is kept in memory and will be written to the PDF output only when its number is referred to by \pdfrefximage or \pdfximage is preceded by \immediate. Nothing is appended to the list being built.

\pdfrefximage appends a whatsit node to the list being built. When the whatsit node is searched at shipping time, PDFT_EX will write the image with number (integer) to the PDF output if it has not been written yet.

► \pdflastximage (read-only integer)

The number of the most recently created XObject image is accessible via \pdflastximage.

▶ \pdfimageresolution (integer)

This parameter specifies the default resolution of included bitmap images (PNG, TIFF, and JPEG). This parameter is read when PDFT_EX creates an image via \pdfximage. When not given or set to 0 PDFT_EX treates it as 72.

7.6 Annotations

PDF level 1.2 provides four basic kinds of annotations:

- hyperlinks, general navigation
- text clips (notes)

- movies
- sound fragments

▶ \pdfannot [\langle rule spec \rangle] \langle general text \rangle

This command appends a whatsit node corresponding to an annotation to the list being built. The dimensions of the annotation can be controlled via Something rule spec. The default values are running for all width, height and depth. When an annotation is written out, running dimensions will take the corresponding values from the box containing the whatsit node representing the annotation. The \langle general text \rangle is inserted as raw PDF code to the contents of annotation. The annotation is written out only if the corresponding whatsit node is searched at the shipping time.

\pdflastannot (read-only integer)

This primitive returns the object number of the last annotation created by \pdfannot. These two primitives allow users to create any annotation that cannot be created by \pdfstartlink (see below).

7.7 Destinations and links

The first type of annotation mentioned before, is implemented by three primitives. The first one is used to define a specific location as being referred to. This location is tied to the page, not the exact location on the page. The main reason for this is that PDF maintains a dedicated list of these annotations —and some more when optimized— for the sole purpose of speed.

\pdfdest \dest spec\

This primitive appends a whatsit node which establishes a destination for links and bookmark outlines; the link is identified by either a number or a symbolic name, and the way the viewer is to display the page must be specified in $\langle \text{dest type} \rangle$, which must be one of those mentioned in table 4.

keyword	meaning
fit	fit the page in the window
fith	fit the width of the page
fitv	fit the height of the page
fitb	fit the 'Bounding Box' of the page
fitbh	fit the width of 'Bounding Box' of the page
fitbv	fit the height of 'Bounding Box' of the page
xyz	goto the current position (see below)

Table 4 The outline and destination appearances.

The specification xyz can optionally be followed by zoom $\langle \text{integer} \rangle$ to provide a fixed zoom-in. The Something integer is like T_EX magnification, i.e. 1000 is the 'normal' page view. When zoom $\langle \text{integer} \rangle$ is given the zoom factor changes to number, otherwise the current zoom factor is kept unchange.d

The destination is written out only the corresponding whatsit node is searched at the shipping time.

\pdfstartlink [\(\rule \) spec \(\)] [\(\attr \) spec \(\)] \(\attr \) action spec \(\)

This primitive is used along with \pdfendlink and appends a whatsit node corresponding to the start of a hyperlink. The whatsit node representing the end of the hyperlink is created by \pdfendlink. The dimensions of the link are handled in the similar way as in \pdfannot. Both \pdfstartlink and \pdfendlink must be in the same level of box nesting. A hyperlink with running width can be multi-line or even multi-

page, in which case all horizontal boxes with the same nesting level as the boxes containing \pdfstartlink and \pdfendlink will be treated as part of the hyperlink. The hyperlink is written out only if the corresponding whatsit node is searched at the shipping time.

Additional attributes, which are explained in great detail in the PDF Reference Manual, can be given via (attr spec). Typically, the attributes specify the color and thickness of any border around the link. Thus /C [0.9 0 0] /Border [0 0 2] specifies a color (in RGB) of dark red, and a border thickness of 2 points.

While all graphics and text in a PDF document have relative positions, annotations have internally hard-coded absolute positions. Again we're dealing with a speed optimization. The main disadvantage is that these annotations do *not* obey transformations issued by \pdfliteral's.

The (action spec) specifies the action that should be performed when the hyperlink is activated while the (user-action spec) performs a user-defined action. A typical use of the latter is to specify a URL, like /S /URI /URI (http://www.tug.org/), or a named action like /S /Named /N /NextPage.

A $\langle goto\text{-action spec} \rangle$ performs a GoTo action. Here $\langle numid \rangle$ and $\langle nameid \rangle$ specify the destination identifier (see below). The $\langle page\ spec \rangle$ specifies the page number of the destination, in this case the zoom factor is given by $\langle general\ text \rangle$. A destination can be performed in another PDF file by specifying $\langle file\ spec \rangle$, in which case $\langle newwindow\ spec \rangle$ specifies whether the file should be opened in a new window. A $\langle file\ spec \rangle$ can be either a (string) or a dictionary. The default behaviour of the $\langle newwindow\ spec \rangle$ depends on the browser setting.

A \langle thread-action spec \rangle performs an article thread reading. The thread identifier is similar to the destination identifier. A thread can be performed in another PDF file by specifying a \langle file spec \rangle .

\pdfendlink

This primitive ends a link started with \pdfstartlink . All text between \pdfstartlink and \pdfendlink will be treated as part of this link. PDFT_EX may break the result across lines (or pages), in which case it will

make several links with the same content.

► \pdflinkmargin (dimension)

7.8 Bookmarks

▶ \pdfoutline ⟨action spec⟩ [count ⟨integer⟩] ⟨general text⟩

This primitive creates an outline (or bookmark) entry. The first parameter specifies the action to be taken, and is the same as that allowed for \pdfstartlink. The \count\ specifies the number of direct subentries under this entry; specify 0 or omit it if this entry has no subentries. If the number is negative, then all subentries will be closed and the absolute value of this number specifies the number of subentries. The \cong text\ is what will be shown in the outline window. Note that this is limited to characters in the PDF Document Encoding vector. The outline is written to the PDF output immediately.

7.9 Article threads

▶ \pdfthread ⟨rule spec⟩ [⟨attr spec⟩] ⟨id spec⟩

Defined an article thread. Treads with same identifiers (spread across the document) will be joined together.

▶ \pdfthreadmargin (dimension)

Specifies a margin to be added to the thread dimensions.

7.10 Miscellaneous

\pdfliteral [direct] \(general text \)

Like \special in normal T_EX , this command inserts raw PDF code into the output. This allows support of color and text transformation. This primitive is heavily used in the METAPOST inclusion macros. Normally PDF T_EX ends a text section in the PDF output and resets the transformation matrix before inserting (general text), however it can be turned off by giving the optional keyword direct. This command appends a whatsit node to the list being built. (general text) is expanded when the whatsit node is created and not when it is shipped out, so this primitive behaves like \special.

▶ \pdfobj [⟨object type spec⟩] ⟨general text⟩

This command creates a raw PDF object that ends op in the PDF file as 1 0 obj << ... >> endobj. When \langle object type spec \rangle is not given, a dictionary object with contents \langle general text \rangle is created.

When however <code>(object type spec)</code> is given as <code>(attr spec) stream</code>, the object will be created as a stream with contents <code>(general text)</code> and additional attributes in <code>(attr spec)</code>.

When $\langle object\ type\ spec \rangle$ is given as $\langle attr\ spec \rangle$ file, then the $\langle general\ text \rangle$ will be treated as a file name and its contents will be copied into the stream contents.

The object is kept in memory and will be written to the PDF output only when its number is referred to by \pdfrefobj or when \pdfobj is preceded by \immediate. Nothing is appended to the list being built. The number of the most recently created object is accessible via \pdflastobj.

▶ \pdflastobj (read-only integer)

This command returns the object number of the last object created by \pdfobj.

▶ \pdfrefobj ⟨integer⟩

This command appends a whatsit node to the list being built. When the whatsit node is searched at shipping time, PDFT_EX will write the object with number (integer) to the PDF output if it has not been written yet.

▶ \pdftexversion

Returns the version of PDFT_EX multiplied by 100, e.g. for version 0.13x it returns 13. This document is typeset with version 14.e.

\pdftexrevision

Returns the revision of PDFT_FX, e.g. for version 0.14a it returns a.

8 Graphics and color

PDFT_EX supports inclusion of pictures in PNG, JPEG, TIFF and PDF format. The most common technique —the inclusion of EPS figures— is replaced by PDF inclusion. EPS files can be converted to PDF by GhostScript, Acrobat Distiller or other PostScript—to-PDF convertors. The BoundingBox of a PDF file is taken from CropBox if available, otherwise from the MediaBox. To get the right BoundingBox from a EPS file, before converting to PDF, it is necessary to transform the EPS file so that the start point is at the (0,0) coordinate and the page size is set exactly corresponding to the BoundingBox. A PERL script (EPSTOPDF) for this purpose has been written by Sebastian Rahtz. The TeXutil utility script that comes with Context can so a similar job. (Concerning this conversion, it handles complete directories, removes some garbage from files, takes precautions against duplicate conversion, etc.)

Other alternatives for graphics in PDFT_EX are:

IMEX **picture mode** Since this is implemented simply in terms of font characters, it works in exactly the same way as usual.

Xy-pic If the PostScript back-end is not requested, Xy-pic uses its own Type 1 fonts, and needs no special attention.

tpic The 'tpic' \special commands (used in some macro packages) can be redefined to produce literal PDF, using some macros written by Hans Hagen.

METAPOST Although the output of METAPOST is POSTSCRIPT, it is in a highly simplified form, and a METAPOST to PDF conversion (written by Hans Hagen and Tanmoy Bhattacharya) is implemented as a set of macros which reads METAPOST output and supports all of its features.

PDF It is possible to insert arbitrary one–page–only PDF files, with their own fonts and graphics, into a document. The front page of this document is an example of such an insert, it is an one page document generated by PDF T_FX .

For new work, the METAPOST route is highly recommended. For the future, Adobe has announced that they will define a specification for 'encapsulated PDF', and this should solve some of the present difficulties.

The inclusion of raw PostScript commands —a technique utilized by for instance the pstricks package—cannot be supported. Although PDF is a direct descendant of PostScript, it lacks any programming language commands, and cannot deal with arbitrary PostScript.

Abbreviations

In this document we used a few abbreviations. For convenience we mention their meaning here.
